

Fundamentals of Programming

CS-114

Lecture 3

What is an Identifier?

- An **identifier** is the **name** to denote **labels, types, variables, constants** or **functions**, in a C++ program.
- C++ is a case-sensitive language.
 - Work is not work
- **Identifiers should be descriptive**
 - Using meaningful identifiers is a good programming practice

a = 3 ,
A = 6 ,
↑

Identifier

- Identifiers must be unique
- Identifiers cannot be reserved words (keywords) X
 - double main return
- Identifier must start with a letter or underscore, and be followed by zero or more letters (A-Z, a-z), digits (0-9), or underscores

• VALID

→ age_of_dog
PrintHeading

_taxRateY2K
ageOfHorse

key-word

• NOT VALID

2000TaxRate

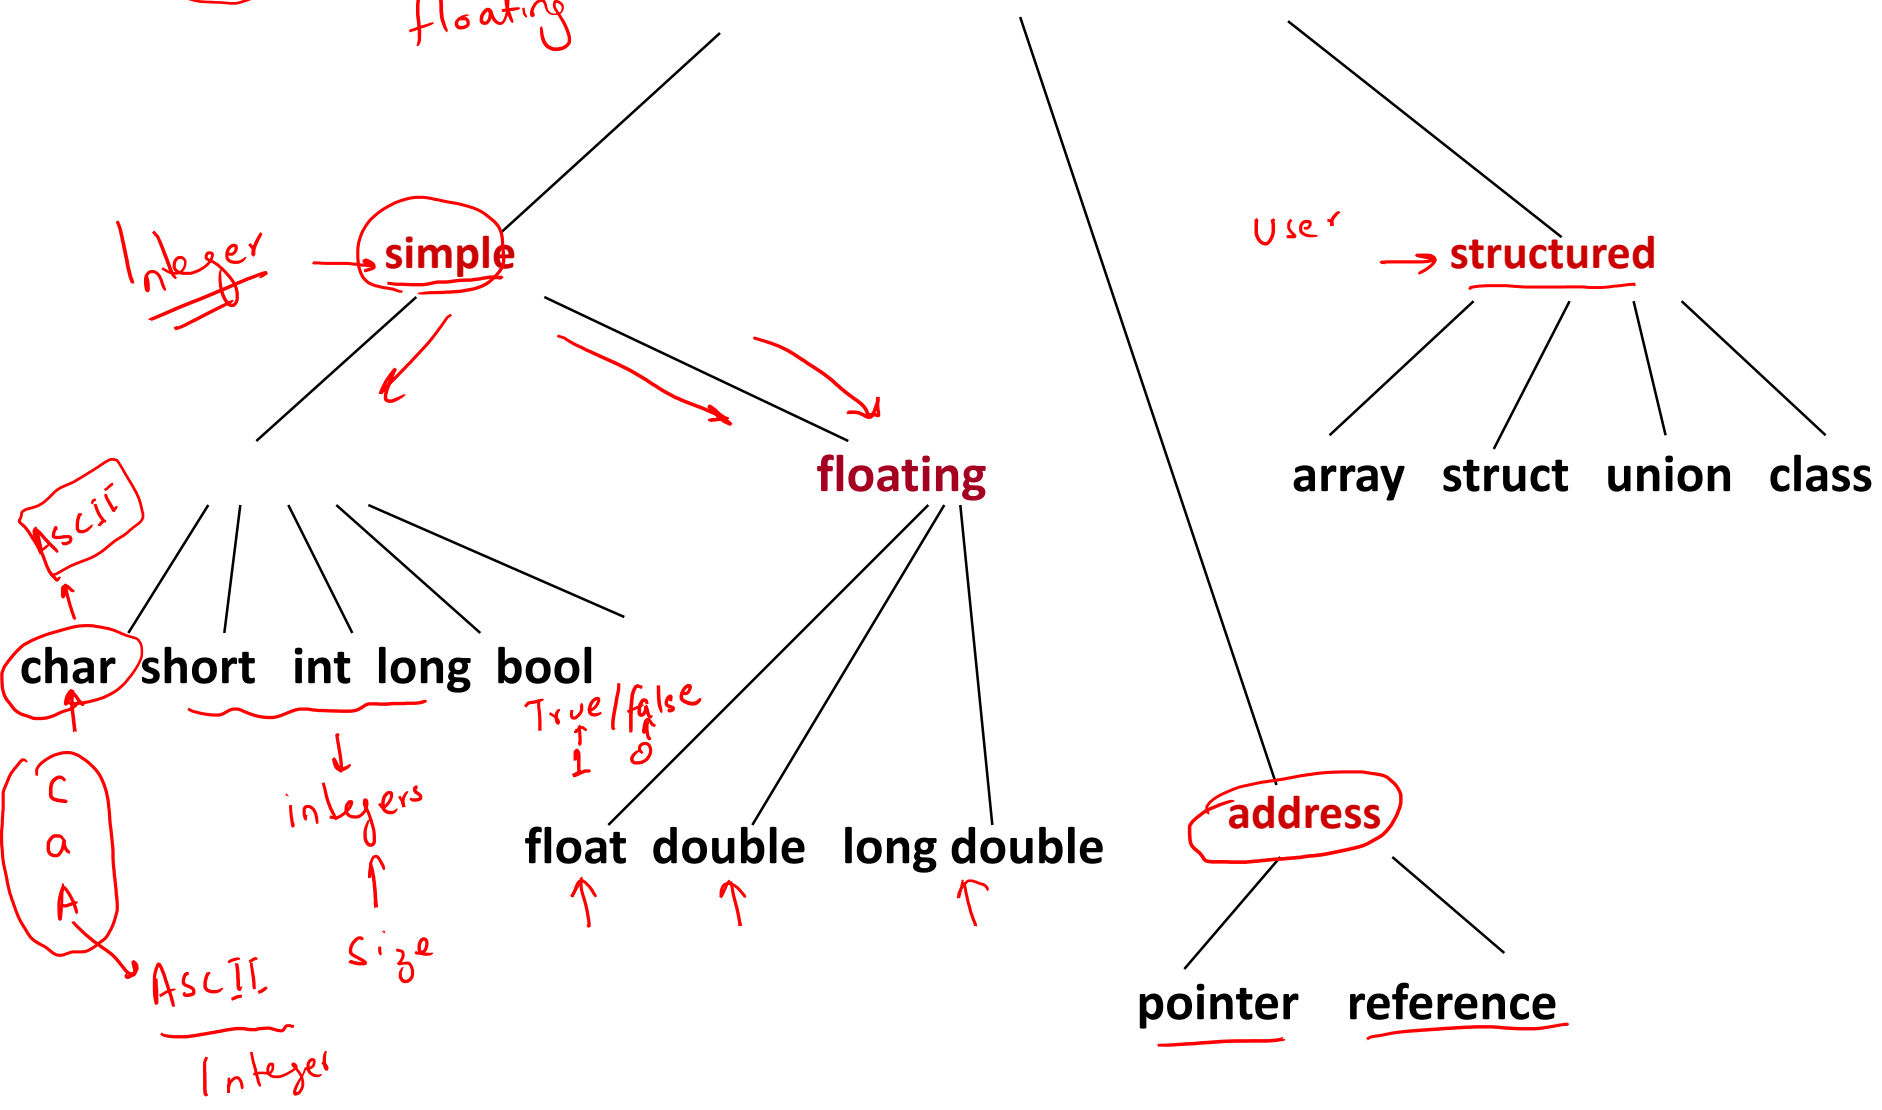

Age-Of-Dog

main X

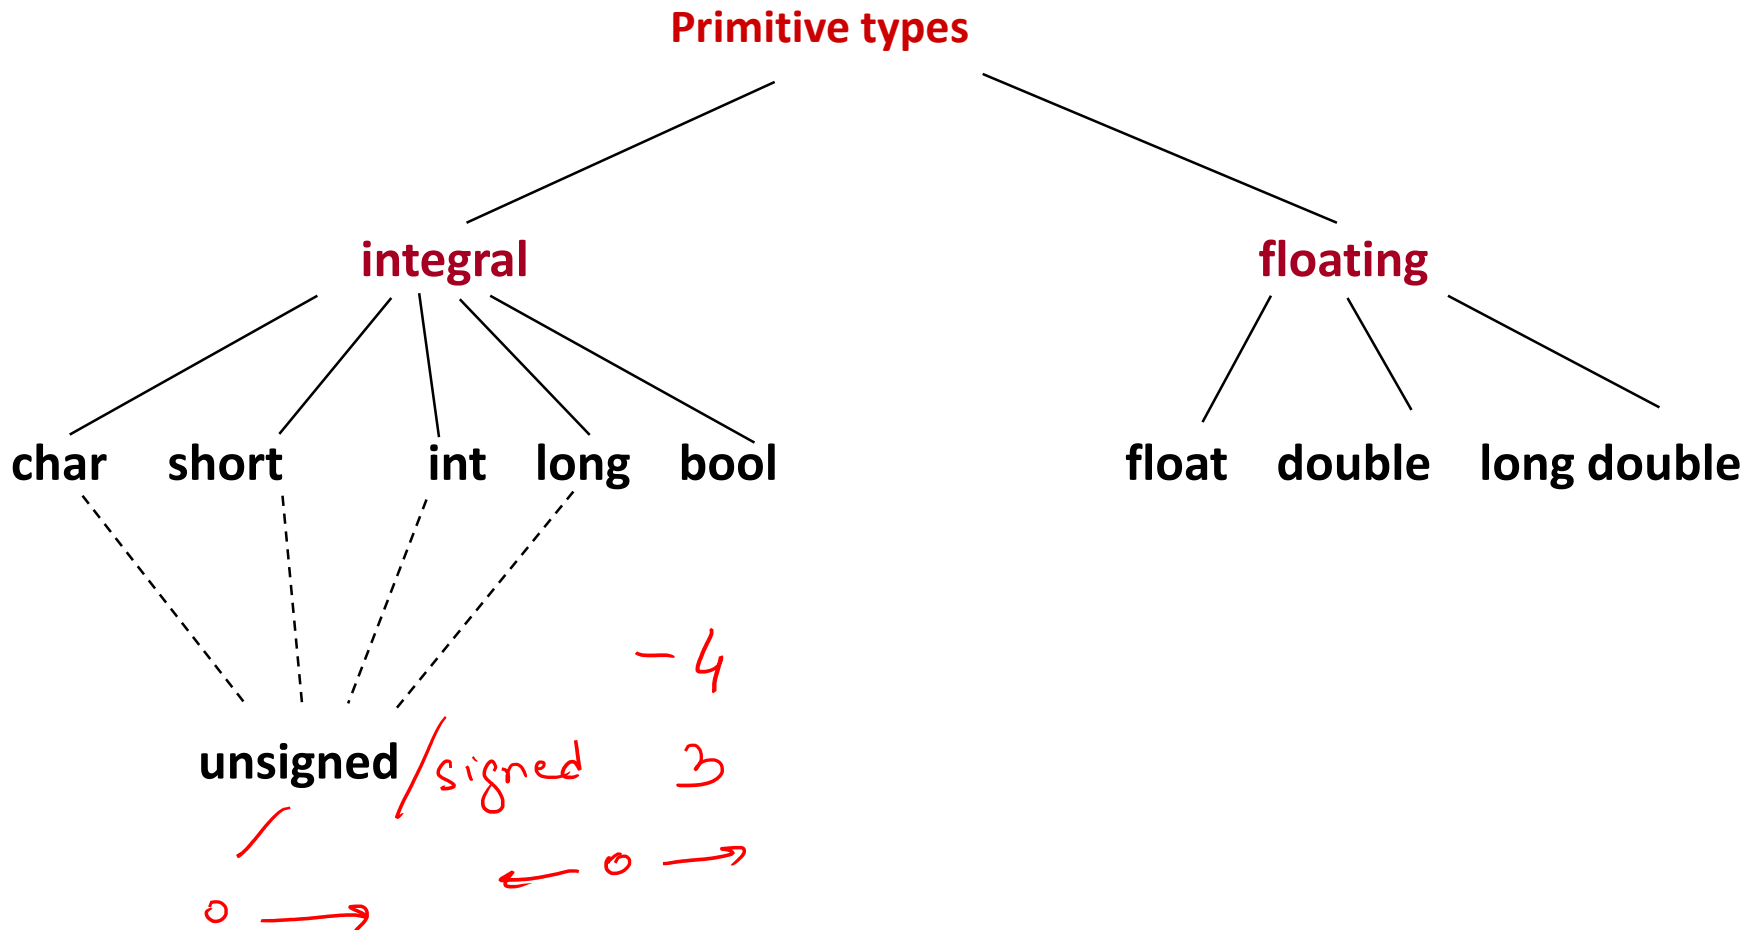

C++ Data Types

value → nature

2 → integer
2.5 → fraction floating

C++ Primitive Data Types

Primitive Data Types in C++

- **Integral Types**
 - represent whole numbers and their negatives
 - declared as `int`, `short`, or `long`
- **Character Types**
 - represent single characters
 - declared as `char`
 - Stored by ASCII values
- **Boolean Type**
 - declared as `bool`
 - has only 2 values `true/false`
 - will not print out directly
- **Floating Types** ←
 - represent real numbers with a decimal point
 - declared as `float`, or `double`
 - Scientific notation where e (or E) stand for “times 10 to the ” (`.55-e6`)

What is a Variable?

- A **variable** is a memory address where data can be **stored** and **changed**.
- Declaring a variable means specifying both its **name** and its **data type**.

What Does a Variable Declaration Do?

- A declaration tells the compiler to **allocate** → **enough memory** to hold a value of this data type, and to **associate the identifier** with this location.

→ Variable Declaration

$c = a + b;$
↑ ↑ ↑
variables

- All variables must declared before use.
 - At the top of the program
 - Just before use.

- Commas are used to separate identifiers of the same type.

```
int count, age;
```

$int\ age;$ → declaration
 $age = 5;$ → initialization
↑ initialize

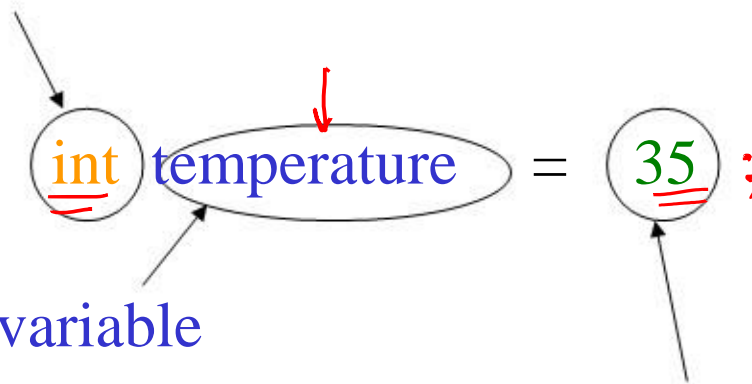

- Variables can be initialized to a starting value when they are declared

```
int count = 0;  
int age, count = 0;
```

$int\ age = 5;$

An Example of a Variable

Type of the variable is integer (written as “int” in C++)

A name of the variable

An initial value of the variable

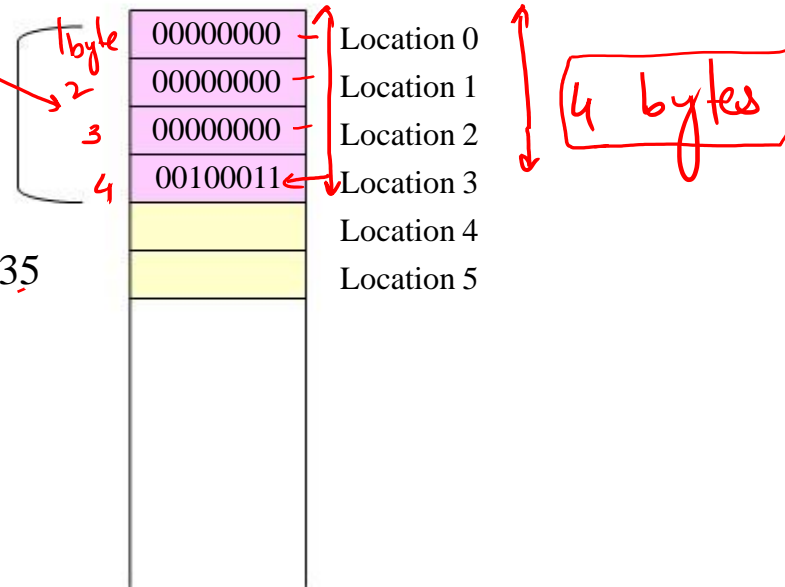

Example of a Variable (Memory View)

`int` temperature = 35

Locations 0 - 3 are collectively called as 'temperature'

`100011` is the binary equivalent of 35

Short int long
~~~~~  
sizes

# Changing the Value of Variable

- Lets change the value of 'temperature'.

# Relative Comparison of int and double

4 bytes ← `int numPeople = 2;`

Reserves 32 bits (4 bytes) and sets the value stored in that space to 2. The name 'numPeople' is associated with this space.

8  
4      4

`double bill = 32.45;`

Reserves 64 bits (8 bytes) and sets the value stored in that space to 32.45. The name 'bill' is associated with this space.

← numPeople

← 8 bytes

4 Int      4 decimal

`double a = 2;`

| Long integer                              | long int                    | 32 bits      | -2147483648 to 2147483647                       |
| Floating point data                       | float                       | 32 bits      | $-1.0 \times 10^{38}$ to $1.0 \times 10^{38}$   |
| Floating point data (with large fraction) | double                      | 64 bits      | $-1.0 \times 10^{308}$ to $1.0 \times 10^{308}$ |
| Text type data                            | char                        | 8 bits       | -128 to 127                                     |
| Boolean data (True or False)              | bool                        | 1 bit        | 1 or 0                                          |

# What is an Expression in C++?

- An **expression** is a valid arrangement of variables, constants, and operators.
- In C++, each **expression** can be evaluated to compute a value of a given type
- In C++, an expression can be:
  - A variable or a constant (count, 100)
  - An operation (a + b, a \* 2)
  - ~~Function call~~ (getRectangleArea(2, 4))

count << (b + c);  
expression

x = 3

a = b + c;

a = 3;

a = b + c;

a = 2a + 2b;  
+ 2c

# Assignment Operator

- An operator to give (assign) a value to a variable.
- Denote as '='  
↑
- Only variable can be on the left side.
- An expression is on the right side.
- Variables keep their assigned values until changed by another **assignment statement** or by **reading in** a new value.

A handwritten diagram illustrating an assignment statement:  $x = a + c;$ . The variable  $x$  is on the left side, and the expression  $a + c$  is on the right side. A red arrow points from the text 'variable' below to  $x$ . Another red arrow points from the text 'expression' below to  $a + c$ . A red arrow also points from the text 'right side' below to the entire right-hand side of the equation.

# Assignment Operator Syntax

- Variable = Expression
  - First, **expression** on right is evaluated.
  - Then the resulting value is stored in the memory location of Variable on left.

NOTE: An automatic type coercion occurs **after evaluation but before the value is stored** if the types differ for Expression and Variable

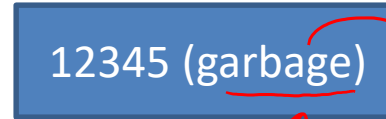

# Assignment Operator Mechanism

- Example: *declaration*  
*initialization*

1 → `int count = 0;`

2 → `int starting;`

3 → `starting = count + 5;`

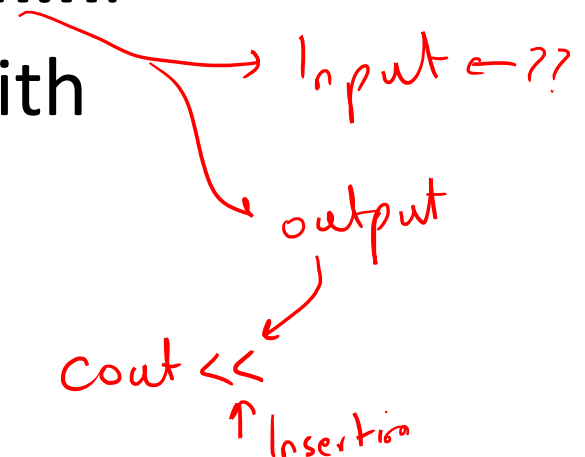

- Expression evaluation:

- Get value of `count`: 0
- Add 5 to it.
- Assign to `starting`

# Input and Output

- C++ treats input and output as a **stream** of characters.
- **stream** : sequence of characters (printable or nonprintable)
- The functions to allow standard I/O are in **iostream** header file or **iostream.h**.
- Thus, we start every program with  
`#include <iostream>`  
`using namespace std;`

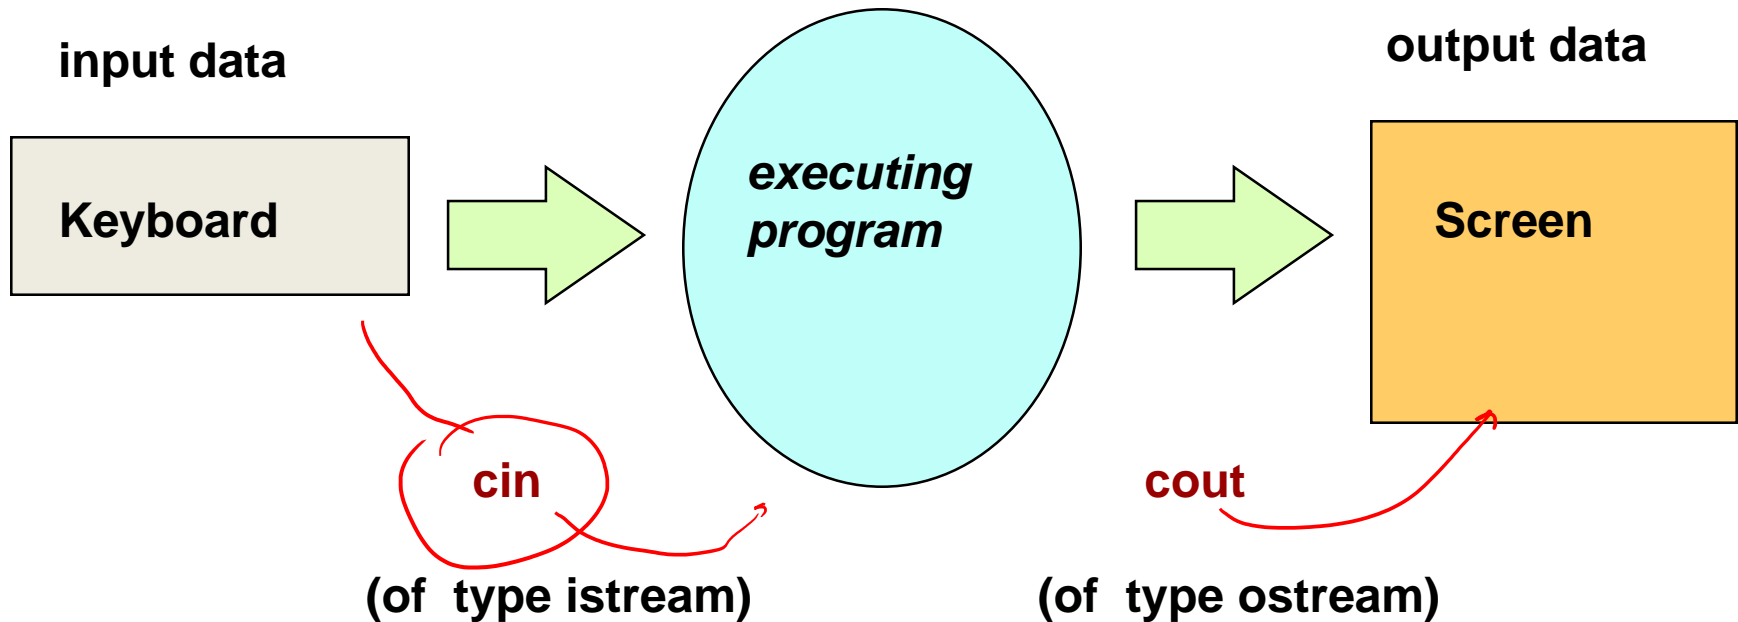

# Include Directives and Namespaces

- **include:** directive copies that file into your program
- **namespace:** a collection of names and their definitions. Allows different namespaces to use the same names without confusion

# Keyboard and Screen I/O

```
#include <iostream>
```

# Insertion Operator ( << )

- Variable **cout** is predefined to denote an **output stream that goes to the standard output device** (display screen).
- The insertion operator **<<** called “put to” takes 2 operands.
- The left operand is a stream expression, such as **cout**. The right operand is an **expression** of simple type or a **string constant**.

# Extraction Operator (>>)

- Variable cin is predefined to denote an **input stream from the standard input device** (the keyboard)
- The extraction operator >> called “**get from**” takes 2 operands. The left operand is a **stream expression**, such as **cin**--the right operand is a variable of simple type.
- Operator >> attempts to **extract** the next item from the input stream **and store** its value in the right operand variable.

# Input Statements

## SYNTAX

*cout << "string";*

```
cin >> Variable >> Variable ...;
```

*>> ↑*

cin statements can be linked together using >> operator.

These examples yield the same output:

```
cin >> x;
```

```
cin >> y;
```

*cout << "string" << "string 2";*

```
→ cin >> x >> y;
```

*↑ ↑*

# How Extraction Operator works?

- Input is not entered until user presses **<ENTER>** key.
- Allows backspacing to correct.
- Skips whitespaces (space, tabs, etc.)
- Multiple inputs are stored in the order entered:

*integer*  
→ **cin >> num1 >> num2;**

User inputs: **3 4**

Assigns **num1** = 3 and **num2** = 4

*a = b + c;*

`int a = 15(6);`  
`// a = 15;`

# Type compatibilities

`char` → 1  
`int` → 4

- **Warning:** If you store values of one type in variable of another type the results can be inconsistent:

- Can store integers in floating point or in char (assumes ASCII value)
- bool can be stored as int: (true = nonzero, false = 0)

- Implicit promotion: integers are promoted to doubles

`double var = 2; // results in var = 2.0`

- On integer and doubles together:

- Mixed type expressions: Both must be int to return int, otherwise float.

`double` → `double` → `int`  
`a = b + c;`  
`int` ↑ `4` `2` + `3` ;  
`7.2`  
implicit

# Type compatibilities (Implicit Conversion)

- The compiler tries to be value-preserving.
- General rule: promote up to the first type that can contain the value of the expression.
- Note that representation doesn't change but values can be altered .
- Promotes to the smallest type that can hold both values.
- If assign **float** to **int** will truncate  
`int_variable = 2.99; // results in 2 being stored in int_variable`
- If assign **int** to **float** will promote to double:  
`double dvar = 2; // results in 2.0 being stored in dvar`

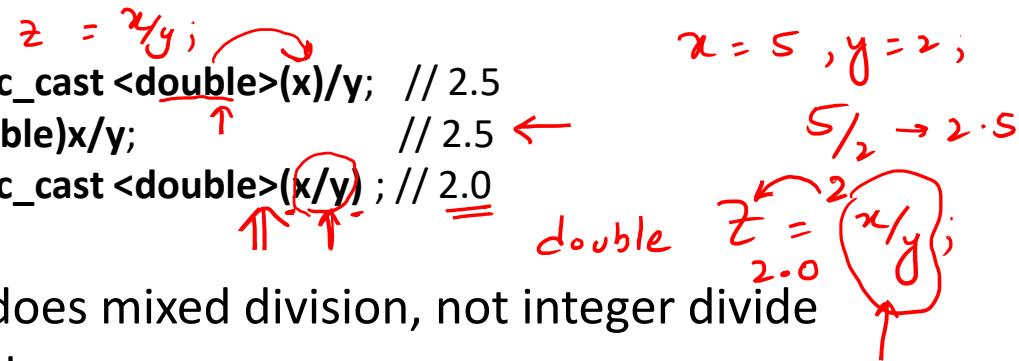

# Type compatibilities (Explicit Conversion)

$3 + (4-1)/(3-2)$   
 ↑  
 Type

- **Casting** - forcing conversion by putting (type) in front of variable or expression. Used to insure that result is of desired type.
- Example: If you want to divide two integers and get a real result you must **cast** one to double so that a real divide occurs and store the result in a double.

```

1. int x=5, y=2; double z; z = static_cast <double>(x)/y; // 2.5
2. int x=5, y=2; double z; z = (double)x/y; // 2.5
3. int x=5, y=2; double z; z = static_cast <double>(x/y); // 2.0
    
```

- converts x to double and then does mixed division, not integer divide
- **static\_cast<int> (z)** - will truncate z
- **static\_cast <int> (x + 0.5)** - will round positive x {use () to cast complete expression}
- Cast division of integers to give real result:

```
int x=5, y=2; double z; z = static_cast <double>(x/y); // 2.0
```

$z = (\text{typename}) \text{ expression}$      2.5  
 $z = (\text{double}) x/y;$

# Operators

$a = a + 1;$       Prog. counter (PC)  $+1$

# Operators

$a = a - 1;$   
 $a += 1;$        $a --;$   
 $\rightarrow a++;$

- “Operators are words or symbols that cause a program to do something to variables.”

$\rightarrow \underline{a} = \underline{a} + b ;$   
 $\rightarrow a + = b ;$

$5 \% 2 = 1$  Remainder

$5 / 2 = 2.5$

## OPERATOR TYPES:

| Type                    | Operators                          | Usage                                                         |
|-------------------------|------------------------------------|---------------------------------------------------------------|
| Arithmetic              | '+' '-' '*' '/' '%' <i>modulus</i> | $a+b$ $a-b$ $a*b$ $a/b$ $a\%b$                                |
| Arithmetic assignment   | '+=' '-=' '*=' '/=' '%='           | $a+=b$ is the same as $a=a+b$<br>$a-=b$ $a*=b$ $a/=b$ $a\%=b$ |
| Increment and decrement | '++' '--'                          | $a++$ is the same as $a=a+1$<br>$a--$ is the same as $a=a-1$  |
| Relational              | '<' '>' '<=' '>=' '==' '!='        | $x == y;$ $x != y;$                                           |
| Logical                 | '&&' '  ' <i>logic gates</i>       | $A \&\& B$                                                    |

*condition*

# Manipulating Values

- Mathematical Operators
  - Common mathematical operators are available in C++ for manipulating values e.g. addition(+), subtraction(-), multiplication(\*), division(/), and modulus (%).
- C++ has many other operators also which we will study in due course.

# Arithmetic Expression Evaluation

- To evaluate an arithmetic expression two concepts need to be understood

## → - Operator Precedence

- Operator precedence controls the order in which operations are performed

## - Operator Associativity

- The associativity of an operator specifies the order in which operations of the same precedence are performed

# Operator Precedence and Associativity

- Operators Precedence and Associativity for C++ is following

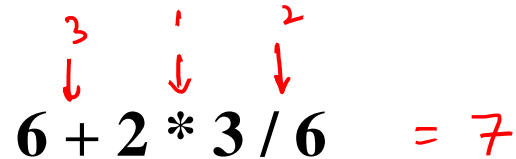

$a/b * c ;$   
→

B D M A S  
↑

1.  $*, /, \%$  → Do all multiplications, divisions and remainders from left to right.
2.  $+, -$  → Do additions and subtractions from left to right.

$a + b - c ;$   
→

# Evaluating an Expression

$$6 + 2 * 3 / 6 = 7$$

- Three operators are in this expression.
- However, \* and / both have the same precedence and + has lower precedence than these two.
- \* and / will be evaluated first but both have the same precedence level.
- Therefore, operator associativity will be used here to determine the first to get evaluated i.e. left to right.
- The left most sub expression will be evaluated followed by the next right one and so on.
- \* will be evaluated first then /

# Arithmetic Operator

| Type       | Operators           | Usage               |
|------------|---------------------|---------------------|
| Arithmetic | '+' '-' '*' '/' '%' | a+b a-b a*b a/b a%b |

- The Modulus Operator

- % is known as the Modulus Operator or the Remainder Operator.
- It calculates the remainder of two variables
- It can only be used with two *ints*..

- **3%2=1**
- **5%2=1**
- **6%3=0**
- **8%5=3**

*1/p number → even / odd*

$$x \% 2 == 0$$

# Arithmetic Operator Precedence and associativity

| Operator(s) | Operation(s)                          | Order of evaluation (precedence)                                                                                                                                                                                             |
|-------------|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ( )         | Parentheses                           | Evaluated first. If the parentheses are nested, the expression in the innermost pair is evaluated first. If there are several pairs of parentheses "on the same level" (i.e., not nested), they are evaluated left to right. |
| *<br>/<br>% | Multiplication<br>Division<br>Modulus | Evaluated second. If there are several, they are evaluated left to right.                                                                                                                                                    |
| +<br>-      | Addition<br>Subtraction               | Evaluated last. If there are several, they are evaluated left to right.                                                                                                                                                      |

# Arithmetic Expressions

- Arithmetic operations can be used to express the mathematic expression in C++:

|                         |                       |   |
|-------------------------|-----------------------|---|
| $b^2 - 4ac$             | $b * b - 4 * a * c$   | ↖ |
| $x(y + z)$              | $x * (y + z)$         |   |
| $\frac{1}{x^2 + x + 3}$ | $1 / (x * x + x + 3)$ | ↘ |
| $\frac{a + b}{c - d}$   | $(a + b) / (c + d)$   |   |

# Polynomials in C++

- In algebra

$$m = \frac{a + b + c + d + e}{5}$$

- In c++

$$m = \cancel{a} + b + c + d + \cancel{e} / 5$$

- What happens if I don't put the parenthesis ()?

# Evaluate

In what order will the expression be evaluated?

Algebra

$$z = pr \% q + w/x - y$$

C++

$$z = p * r \% q + w/x - y$$

↓ ↓ ↓ ↓ ↓ ↓

(Deitel and Deitel (5<sup>th</sup> Ed), fig 2.12)

# Logical Operators

| Type    | Operators | Usage |
|---------|-----------|-------|
| Logical | '&&' '  ' |       |

- Logical operators are carried out on statements, e.g. statement1 && statement 2, etc.
- Logical AND (&&)
  - false && false= false
  - false && true = false
  - true && false= false
  - true && true = true
- Logical OR (||)

# Logical Operators

- Logical OR (||)
  - false || false = false
  - false || true = true
  - true || false = true
  - true || true = true
- Logical NOT (!)
  - !false = true
  - !true = false

| Expression                                                      | True or False |
|-----------------------------------------------------------------|---------------|
